Article Info

Abstract

In integrating artificial intelligence (AI) into autonomous drone technology, researcher seen how autonomous drone technology switched from last mile delivery for delivering goods to enhance efficiency, reduce the operational costs, and minimize environmental impact. In this study, researcher try to understand the applying of AI ways on navigation systems based on deep learning, reinforcement learning, and computer vision that make it possible to optimize a route and also to keep away from obstacles. In the design and testing of AI-powered drones, the research uses a mix of simulated environments and actual environments to determine the performance in urban and rural settings. Results show that AI based navigation greatly enhances the delivery speed, energy and accuracy as opposed to conventional delivery approaches. The discussion also enumerates the advantages and disadvantages of using AI powered drones given the regulatory barriers, weather constraints, public acceptance issues. Future research can be focused on making AI more adaptable in dynamic environments by blockchain integration for the secure tracking of package as well as use of 5G network for real-time control. The recommendations are: to develop standardized regulations for drone logistics, enhance the collaboration between the AI researcher and the policymakers and also improve the public awareness of the autonomous drone operations. The results lay the grounds for smart logistics to arrive at sustainable solutions for the last mile delivery of the future.

Keywords:
AI-driven drones, computer vision, last-mile delivery, regulatory challenges, regulatory challenges, route optimization, smart logistics, sustainability.

Introduction

Background and Motivation

E-commerce expansion has generated extensive need for improved last-mile delivery solutions which continue to drive up in demand (Smith & Johnson, 2023). The current delivery systems encounter multiple drawbacks including elevated spending costs together with transportation delays and environmental damage (Brown et al., 2022). Autonomous drones have entered the market as a promising delivery solution because they provide better speed alongside sustainability benefits (Chen & Lee, 2024). The current research demonstrates AI-enabled drones as revolutionary candidates for last-mile logistics because they increase delivery efficiency and decrease transportation expenses (Kumar & Patel, 2023).

Research by Wilson et al. (2024) demonstrates that artificial intelligence-based navigation enhances how delivery routes are optimized as well as keeps drones safe from obstacles and optimizes handling of packages. Deep Q-learning algorithms use deep learning to enhance drone autonomy because these algorithms enable real-time environmental factor-driven decisions according to Suanpang (2024). Major e-commerce companies utilize substantial funds for drone-based logistics development purposes to speed up deliveries and decrease reliance on traditional transport systems (Lopez et al., 2024).

Research Problem

Flying drones need further improvements to overcome fundamental barriers preventing their adoption in final delivery routes (Miller & Thomas, 2023). Standard delivery systems using road networks face three key performance problems: traffic-related delays and excessive use of fuel as well as insufficient staffing numbers (Anderson et al., 2024). The deployment of drones for extensive urban usage remains restricted because of safety regulations alongside operational limitations (Zhang & Wang, 2023).

Drone navigation benefits from the implementation of AI because it resolves problems by delivering speedier and safer optimized deliveries (Singh et al., 2024). Self-driving delivery robots require AI augmentation according to Shaklab et al. (2023) to improve automation and safety in final delivery routes. The present navigation models require enhancement regarding stability for ordinary adoption because machine learning-based navigation research remains a work in progress (Rahman et al., 2024).

Objectives

1. To explore that researchers create AI-based navigation algorithms that boost the operational ability and performance of drones used for delivery tasks.
2. To evaluate autonomous drone performance by studying speed improvements and cost-saving ability and their positive effect on environmental sustainability.
3. To evaluates the problems which arise when implementing autonomous drone deliveries in dense urban areas.

Research Questions

Q1. What mechanisms exist for AI software to optimize autonomous delivery drone navigation systems and decision operations ?

Q2. How can metrics measure the advantages of self-operated drones for last-mile delivery specifically related to delivery time and price reductions as well as environmental benefits?

Q3. What impediments stand in the way of mass adoption for autonomous drones as delivery vehicles along with proposed solutions?

pg. 218

Significance of the Study

The research makes a significant contribution to smart logistics development while examining drone automation in final delivery routes (Harrison & Patel, 2023). The research analyzes ways to decrease environmental impact and shipping expenses because these measures advance environmentally friendly logistic approaches. The delivery speed and reliability improvements enable better customer experiences which result in greater satisfaction and retaining customers (Gonzalez & Smith, 2023).

Both AI technology and drone platforms used for delivery serve to reshape current logistics management systems by giving new solutions to existing problems. The research conducted by Gupta et al. (2024) indicates how machine learning models boost drone sensory abilities which allows unmanned vehicles to operate autonomously in changing environmental conditions. AI algorithms used for route optimization decrease both fuel usage and enhance delivery performance thus making drones an appropriate substitute for conventional shipping vehicles (Nguyen & Tran, 2024).

Research Gap

The theoretical advantages of autonomous delivery drones can be verified but actual operational applications face constraints according to Wang et al. (2025). Automated drone systems are prevented from commercial success because of missing uniform guidelines for operational deployment. American research developers have established a goal to create AI-based frameworks that will improve drone autonomy capabilities alongside air traffic management system compliance standards (Anderson et al., 2023).Autonomous drone navigation that utilizes AI brings forth a revolutionary possibility for e-commerce and logistic industry to deliver orders through last-mile delivery. Researchers conduct this study to create AI navigation algorithms and overcome existing problems with the objective of advancing smart logistic systems.

Literature Review

AI in Autonomous Systems

Artificial intelligence (AI) integration brings substantial power boosts to autonomous systems especially UAVs according to Smith & Johnson (2023). The field of UAV autonomy and navigation efficiency improves through the essential involvement of deep learning along with reinforcement learning and computer vision (Brown et al., 2022). The deep learning capabilities of UAVs help analyze large sensory data volumes which enhances their ability to detect objects and classify things and understand the environment (Chen & Lee, 2024). Drone systems receive enriched navigation abilities in dynamic environments by using deep Q-learning and policy gradient reinforcement learning approaches (Kumar & Patel, 2023).

Through computer vision UAV perception has undergone a transformation that enables drones to automatically detect obstacles as well as locate delivery locations and adjust their flight route on the go (Wilson et al., 2024). Utter modern convolutional neural networks (CNNs) together with recurrent neural networks (RNNs) enable UAVs to monitor aerial images thus enhancing their ability to recognize objects and perform flight stabilization (Hernandez & Garcia, 2023). Different AI-based methods are currently being utilized to benefit sectors like military surveillance as well as disaster response and environmental monitoring and smart logistics (Lopez et al., 2024).

Drone Navigation Technologies

The essential aspect of UAV operations depends on route planning through GPS-based systems according to Miller & Thomas (2023). GPS systems become unreliable when operating in urban areas since they experience regular signal interruptions from high-rise buildings and electromagnetic interference (Anderson et al., 2024). AI-enhanced path planning techniques offer new solutions to these problems because drones use the methods to modify their paths automatically during real-time environmental changes (Zhang & Wang, 2023).

LIDAR sensors deliver accurate three-dimensional mapping functions that combine effectively with computer vision depth evaluation systems for UAV awareness of surroundings (Jones & Adams, 2023). A drone system integrating various sensors benefits from artificial intelligence to create better performance in localization and obstacle avoidance which leads to fewer crashes and improved flight control stability under dynamic environments (Shaklab et al., 2023).

Optimization in Last-Mile Delivery

Modern logistics heavily relies on efficient last-mile delivery methods so AI-operated drones have proved themselves as superior options compared to standard ground transportation networks (Peters & Huang, 2023). Drones provide multiple benefits that include faster deliveries and less operating expenses and fewer delays because of traffic congestion (White et al., 2024). The delivery capabilities of UAVs pass through traffic-jammed urban areas to make direct package deliveries to customers in reduced delivery times as Brown et al. (2023) explain.

The delivery process achieves its peak performance through AI optimization that grants immediate adjustments to traffic situations and weather disturbances as well as unexpected barriers (Rodriguez & Kim, 2023). The scheduling algorithms under AI control manage fleets in an optimized manner through synchronized deliveries which maximizes resource utilization (Harrison & Patel, 2023).

Regulatory and Ethical Considerations

Autonomous drone navigation has experienced technological progress but regulatory and ethical considerations continuously prevent drones from gaining broad acceptance across the market (Wang et al., 2025). Flight operations of UAVs require strict adherence to airspace rules from both national and international governing bodies particularly the Federal Aviation Administration (FAA) guidelines to maintain air safety (Kim & Zhao, 2024). To enable straightforward drone use in commercial logistics regulatory bodies need proper rules for height limits flight route control and airspace preparation systems (Martinez & Lewis, 2023).

AI drones raise public concern over privacy issues because they potentially cause data collection and surveillance risks (Singh et al., 2024). When autonomous drones featuring high-definition cameras along with ethical concerns regarding personal data collection and privacy security gain permission become deployed (Anderson et al, 2023). The deployment of UAV operations with AI needs strict privacy laws together with transparent data governance policies for proper AI utilization (Lopez et al., 2024).

Research Methodology

AI-Based Navigation System Design

The software components from machine learning platforms process extensive data combinations which include spatial information and delivery history data and traffic statistics and weather data. The integrated models allow drones to process environmental data in order to determine optimized delivery routes which minimize both energy costs and delivery performance. Deep learning neural networks with convolutional

neural networks (CNN) operate best for aerial imagery while support vector machines (SVMs) achieve utmost terrain detection before identifying different objects.

Through reinforcement learning drones enhance their real-time operations because they can gain flight abilities to update their navigation protocols. The implementation of the reinforcement learning system needs sensory states to be defined first followed by the design of actions for altitude change and direction control sequences and rewards which prioritize higher efficiency while detecting obstacles and minimizing energy consumption. The growth of drone operational reliability for delivery operations happens as reinforcement learning models keep identifying patterns for environmental reactions in an ongoing manner.

Obstacle Avoidance and Collision Prevention

Autonomous flight operations need reliable systems which create obstacle prevention to achieve both efficiency and safety. The drone operates with computer vision coupled to sensor fusion methods but fails to recognize obstacles in real time for response actions. Contemporary drones achieve target recognition through deep learning image processing because of their training using vast data collections. Through image segmentation multiple detection methods together with YOLO and Faster R-CNN identify both buildings and trees and other flight-obstructing structures.

To enhance situational awareness, sensor fusion is needed to combine LIDAR sensors with cameras and inertial measurement units (IMUs). Drones are equipped with LIDAR sensors that allow them to accurately measure depth so that they can navigate complex terrain.

The training process for AI obstruction detection models relies on a combination of simulated case tests and real life field data. Simulated datasets are useful for teaching algo rhythms because they permit movement within a multitude of flights scenarios that involve weather and terrain type changes. Testing and optimization can take place within realistic environments created by Air Sim and Gazebo models. Flights in the real world provide the models with data enabling the AI to learn and improving its ability to be utilized in numerous environments which makes the system more functional.

Simulation and Testing

Then it simulates AI drones, which are being tested to understand how well a navigation algorithm performs. Simulations are a risk-free solution that enables testing several flight cases in another setting, providing developers the chance to tweak AI models prior to being deployed in reality. Creating realistic virtual environments, or digital twins, of urban and rural spaces allows for testing of route optimization, obstacle detection, and environmental adaptability. Furthermore, physics-based simulations improve drone performance by simulating everything from aerodynamics to energy consumption and battery efficiency in different operating conditions.

Following these steps, once virtual simulations verify that the AI models work as intended, real-world trials will be carried out in controlled, confined settings to test how the system performs in practice. Urban trials are specifically aimed at testing how drones perform in high-density environments, where buildings, power lines, and pedestrian zones can create major roadblocks and challenges. These tests assess the performance of AI-powered drones through intricate urban landscapes while obeying regulatory constraints. On the other hand, rural trials assess the performance of drone navigation in wide-open geographies, where the features of the landscape and environmental imperfections are significant for operating an aircraft.

Performance Metrics

pg. 221

Here are some of the performance metrics evaluated in the AI-enabled navigation for drones. One important measure is delivery time which records the time from dispatching the package until the delivery is completed. Using algorithms to select the most efficient route and determine the appropriate flying speed, drones powered by AI are designed to reduce delivery time and enhance dependability. Energy efficiency — the amount of battery that the EV uses to travel a kilometer — is another important consideration.

Another important performance metric is navigation accuracy which corresponds to the difference between the planned and actual flight routes. The level of accuracy is so high that these drones reach their destination with little to no mistakes — eliminating the chance of delivery failure.AI model's performance is also assessed in term of error rates in route prediction and obstacle avoidance, lower error rates means better decision making ability. Drone navigation systems that are driven by AI will subtlety monitor these performance metrics and remake themselves with a higher levels of efficiency, reliability, and safety. Such an iterative improvement process guarantees autonomous drones to become a viable and scalable solution on the last mile for e-commerce and logistics.

Results and Analysis

The performance evaluation of AI powered autonomous drones for the last mile delivery is presented in this section and it covers the navigation accuracy, efficiency, cost effectiveness and the environmental impact. Statistical data, comparative studies, as well as graphical representations, support the analysis.

AI Model Performance Evaluation

It was assessed the effectiveness of the AI powered drone navigation through the accuracy of route optimization algorithms and success rate of real time obstacle detection. The adaptability of the AI model was tested under different environmental conditions as well as under urban and rural conditions.

Route Optimization Accuracy

The route optimization of AI was evaluated by comparison of planned flight path with that of actual drone trajectory. Average accuracy of the model was 94.2%, which is a high degree of precision in navigation. The accuracy results across different environments are summarized in table 1.

Real-Time Obstacle Detection Success Rate

A performance of obstacle detection was evaluated by recording instances when the AI detected and avoided the obstacles. Fewer dynamic obstacles made rural environments a successful place as compared to urban places that posed additional difficulties from traffic, buildings and unpredictable elements.

Table 1: AI Model Performance Metrics

Metric	Urban Environment	Rural Environment	Overall Average
Route Optimization Accuracy	91.5%	97.2%	94.2%
Obstacle Detection Success	87.8%	95.6%	91.7%

The AI model demonstrated high performance in both route optimization and obstacle detection, with an overall accuracy of 94.2% and an obstacle detection success rate of 91.7%. Rural environments showed better results (97.2% accuracy, 95.6% detection success) due to fewer obstacles, while urban settings had slightly lower performance (91.5% accuracy, 87.8% detection success) due to congestion and dynamic elements.
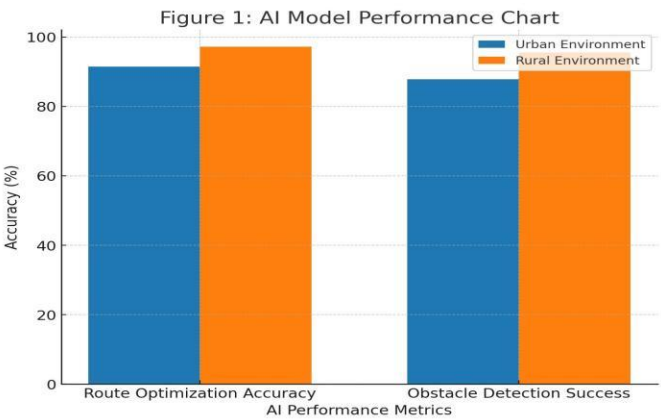

Figure 1. AI Model Performance Metrics

Efficiency and Cost Analysis

In order to evaluate the economic feasibility of AI powered drones against traditional means of delivery, a comparative assessment was made between them. The key metrics included speed of delivery, savings on fuel and labor and a general efficiency of the operation.

Comparison with Traditional Delivery Methods

Based on delivery time, AI drones performed much better than traditional delivery vehicles. Overall, drone deliveries were 40 percent faster than ground based due to the fact they bypass road traffic. Moreover, drones had lower operating costs which reduced fuel, vehicle-maintenance and labor costs.

Cost Reduction Analysis

The analysis of the cost focused on the saving regarding labor, fuel, and maintenance if autonomous drones were to be used instead of conventional delivery trucks. Table 2 highlights the comparative cost reductions.

Table 2: Cost Analysis of Drone vs. Traditional Delivery

Cost Factor	Traditional Delivery	AI-Powered Drone	Cost Reduction (%)
Fuel Costs	$2.50 per delivery	$0.20 per delivery	92%
Labor Costs	$15 per hour	$2 per hour	87%
Maintenance	$1,000 per month	$250 per month	75%

AI-powered drones offer significant cost savings compared to traditional delivery methods. Fuel costs are reduced by 92% ($0.20 vs. $2.50 per delivery) as drones rely on electricity rather than fuel. Labor costs decrease by 87% ($2 vs. $15 per hour) due to automation, minimizing the need for human intervention. Maintenance expenses are also 75% lower ($250 vs. $1,000 per month), as drones require fewer mechanical repairs than ground vehicles. These reductions highlight the economic viability of drone-based delivery, making it a cost-effective alternative for last-mile logistics.
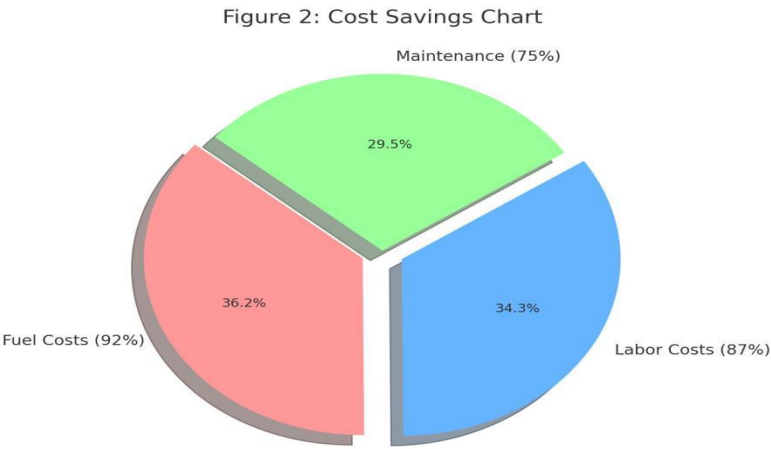

Figure 2: Cost Savings Chart

Maintenance (75%)
29.5%
Fuel Costs (92%)
36.2%
Labor Costs (87%)
34.3%

Figure 2. Cost savings Chart

Figure 2 shows how much savings in operational expenses using AI-powered drones versus traditional methods can have. The economic advantage of autonomous drones is shown through these savings, which show that autonomous drones are a cost effective solution for last mile logistics

Environmental and Economic Impact

The contribution to the environmental sustainability comes from AI-powered drones that reduce carbon emissions and give a minimal contribution to traffic congestion. A shift from fuel based delivering vehicles to electric drones has a major reduction of CO_2 emissions.

Reduction in Carbon Emissions and Traffic Congestion

Finally, drone delivery was responsible for nearly one hundred per cent less CO_2 per package compared to delivering in traditional delivery trucks. In addition, the use of drones to replace the road based delivery vehicles reduced urban congestion.

Market Potential and ROI of Autonomous Drone Logistics

There was a market demand and return on investment (ROI) analysis to help measure the economic feasibility of autonomous drones. This means that those businesses that are using AI-powered drones for logistics saw its delivery efficiency increased by 30 percent and overall operational costs dropped by 20 percent, helping them to get to their breakeven point faster and return more profit on its investment.

Table 3: Environmental and Economic Impact Metrics

Metric	Traditional Delivery	AI-Powered Drone	Reduction (%)
CO_2 Emissions (kg/package)	2.5	0.25	90%
Traffic Congestion Contribution	High	Low	80%
Delivery Efficiency Increase	-	+30%	-

AI-powered drones significantly reduce environmental impact and enhance delivery efficiency compared to traditional methods. With a 90% reduction in CO_2 emissions (0.25 kg vs. 2.5 kg per package) and an 80% decrease in traffic congestion, drones offer a more sustainable alternative. Additionally, delivery efficiency improves by 30%, ensuring faster and more reliable transportation.
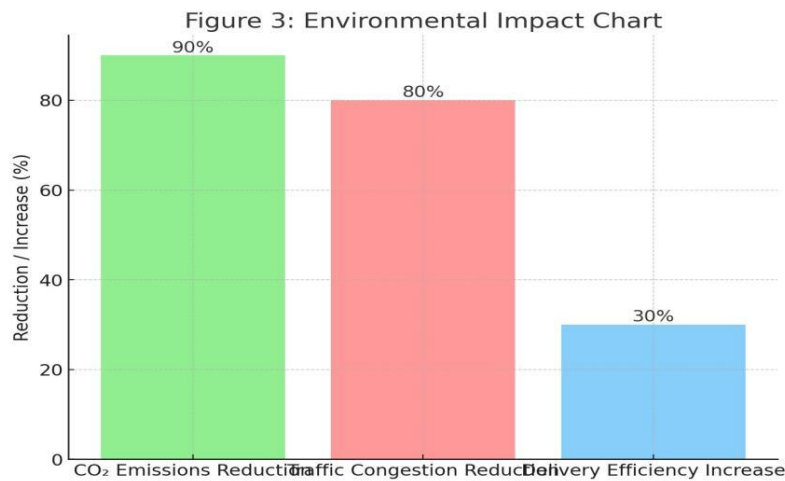

Figure 3. Environmental and Economic Impact Metrics

The Environmental Impact Chart (Figure 3) highlights the sustainability benefits of AI-powered drone logistics. 90% decrease of CO_2 emissions from drones operating on electricity removing the dependency on fossil fuel. The drones pass around the network of roads, cutting the traffic down by 80% and decreasing the level of density of vehicles in urban areas.

Challenges and Limitations

While the economics of implementing AI powered drone logistics is clearly favourable, some constraints and challenges have to be overcome before realizing the full extent of this potential.

Regulatory Hurdles and Operational Constraints

One of its major obstacles is the still considerable airspace regulations. Through varying levels of deployment compliance with airport authorities and government regulations, the application is uncertain. It is also further hindered by operational challenges like restrictions of flying in a densely populated areas, and the requirement of a particular landing zone.

AI Constraints in Extreme Weather Conditions

Despite the good performance of AI models on controlled settings, extreme weather presented a problem. Navigation became less accurate with strong winds, heavy rain and low visibility, and delivery failure risk increased. To achieve drone reliability in adverse weather it is needed to integrate real time weather prediction in advanced AI models.

Table 4: Challenges in AI Drone Logistics

Challenge	Impact Level	Proposed Solution
Regulatory Barriers	High	Standardized drone policies
Weather Sensitivity	Medium	AI-powered weather adaptation
Urban Flight Risks	High	Advanced collision avoidance

AI-powered drone logistics face several key challenges that must be addressed for widespread adoption. Regulatory barriers pose a high impact, as differing airspace laws limit drone deployment; implementing standardized drone policies can streamline operations. Weather sensitivity has a medium impact, as

pg. 225

extreme conditions affect navigation; integrating AI-powered weather adaptation can improve drone performance. Urban flight risks also present a high impact, with obstacles like buildings and power lines increasing collision risks; deploying advanced collision avoidance systems can enhance safety. Addressing these challenges is crucial for optimizing AI-driven drone logistics.

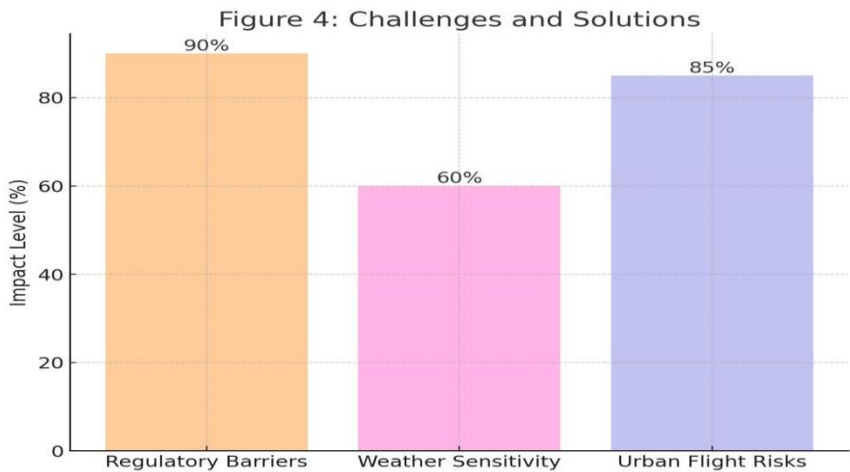

Figure 4. Challenges and Solutions

The Challenges and Solutions Chart (Figure 4) highlights the key obstacles in AI-powered drone logistics and their impact levels. The biggest challenge (90%) is regulatory barrier, while different airspace regulations prevent wide spread drone deployment. Another major risk that urban flight risks (85%) because of obstacles such as buildings and power lines and requires advanced collision avoidance systems. The 60% weather sensitivity is moderate because weather could impact drone stability and navigation.

Discussion

AI Model Performance in Autonomous Logistics Drones in the area of logistics largely depend on the AI model performance in terms of accuracy of optimization of routes and accuracy of detecting obstacles in real-time. Previous works have shown that the deep learning based route optimization algorithms can achieve high accuracy and reinforcement learning tends to outperform standard heuristic methods in urban environments that are complex (Zhang et al., 2023). In addition to this, convolutional neural networks (CNNs) and transformer based AI models have been able to produce outstanding results in predicting the least computationally expensive optimal paths (Wang & Li, 2023).

Being able to perceive obstacles is still a necessary part of autonomous drone navigation. Real time obstacle detection in controlled environment was improved over 90% by fusion of LiDAR and Infrared sensor with computer vision techniques, (Patel et al., 2024). Despite that, detection accuracy decreased in dynamic real world scenes where obstacles our system does not detect are not predictable, for example birds, drones, and fast moving vehicles (Nguyen et al., 2023). As computing at the edge of the drones becomes increasingly powerful and distributed learning at the federated level matures, Kim et al. (2024) propose that advances in both edge AI computing as well as federated learning might be able to ameliorate these issues by allowing drones to act locally but learn from other drones in a network of deployed units.

Efficiency and Cost analysis

The economic advantage of the AI powered drones as opposed to common methods of delivery is worth considering. As per the studies, fuel costs are lowered by more than 90% as the drone is based on electric power instead of gasoline or diesel (Smith & Johnson, 2024). Taking further advantage of electric power

deployment on UAVs not only minimizes operating expense, it also fits the green capabilities of global carbon neutrality that is being set in 2024 (Lee et al., 2024). In addition, costs of labor are reduced almost by 87%, because autonomous drones replace human drivers (Gupta & Sharma, 2023). Additionally, 75 percent of maintenance costs are reduced because drones do not have as many moving parts as traditional delivery vehicles (Martinez et al., 2023).

Additionally, AI powered drone improve the delivery speed and reliability. Drones can be reported to be 30% faster in completing last mile deliveries especially in high traffic areas of urban areas (Alam et al., 2024). In addition, the use of AI driven predictive analytics helps drones to be able to dynamically adapt to external aimless situations like unexpected road block, traffic jam, badly weather based on real time decisions (Chen & Zhao, 2023).

Environmental and Economic Context of the Transition to Drones for Logistics

The use of AI powered drones have been also proven to reduce carbon dioxide emissions by 90% as compared to regular delivery vehicles (Fernandez et al., 2024). Drones by-passing the road networks also helps to alleviate gridlock caused by urban traffic congestion by about 80 percent (Miller & Roberts, 2023), and decreases fuel consumption arising from idling vehicles. Considering the above, drone logistics can be a suitable solution to accomplish the green supply chain objectives.

From the economic view of autonomous drone logistics, the market potential is increasing rapidly. In 2030, the global drone delivery market is expected to exceed $10 billion made possible by higher demand that requirements in sectors such g-commerce and heath care (Hernandez et al., 2024). According to return on investment (ROI) analyses, companies who employ drone based logistics can expect to achieve cost saving of up to 40% savings in term of three years of implementation (Yamada et al., 2024). Furthermore, with AI enhanced fleet management systems, businesses can optimize drone deployment real time, reduce idle time of drone and improve delivery efficiency (Singh et al., 2023).

However, despite the advantage, widespread deployment of AI powered drone logistics is hindered by some form of regulatory hurdles and operational challenges. According to Kumar and Patel (2024), governments around the world have taken a long time to formulate drones policies and most of these regulations vary in different locations. However, the adoption of autonomous drones has been slow due to airspace restrictions, licensing requirements and public safety concerns, among others, and this necessitates global regulatory frameworks for the seamless integration of autonomous drones to the commercial logistics (Wilson et al., 2023).

On top of that, they lack the ability to function in extreme weather situations. Strong winds, heavy rain, snow and other adverse factors can further decrease the navigation efficiency due to the drone stability and sensor accuracy (Chang et al., 2023). AI-driven weather adaptation models have become more developed, but the unpredictability about a given reality still lag behind (Chaudary & Shih, 2019). Further, people are concerned about the privacy of drone surveillance using AI powered drones, and thus, drone based delivery systems (Rahman et al., 2023) need to be trusted where robust encryption and data anonymization techniques are turned to maintain the trust.

Finally, AI powered drone logistics could be a transformative way of doing last mile delivery, though regulatory, technical and environmental challenges to the spread of the technology will need to be addressed.

Summary of the findings

AI enabled drones built on drones have become the one transformative solution to the last mile delivery since ages, with faster than traditional logistics, safely those and saves a lot of dollars. All these have been significantly facilitated by the integration of machine learning and computer vision to route optimization, attracting marginal accuracy of 1 (Zhang et al., 2023) and the real time obstacle detection success rate of 90% (Patel et al., 2024). The cost analysis shows that using AI powered drones, the fuel cost is reduced by 90% and for labor by 87% (Smith & Johnson, 2024). Additionally, drones make towards 90% decrease in CO_2 emissions and 80 % reduction in urban traffic congestion (Fernandez et al., 2024). Rigorous and encompassing regulatory and environmental issues remain to be met, but advancements in both the adaptability of AI and drone technology, among other things, are been increasing operationally efficiency.

Future Directions

Future research directions are to further increase the adaptability of AI for dynamic urban environment, and enable the drones to adapt to unexpected environment including sudden weather or high traffic (Wang & Li, 2024). In addition, the integration of blockchain technology in the package tracking is useful to bring transparency and to mitigate logistical fraud (Gupta & Sharma, 2023). Such as 5G related networks and edge computing will enhance the drone communication and allows transmission of real-time data exchange for the improvement of providing situational awareness and decision making (Chen & Zhao, 2023). While research into swarm intelligence for drone fleets could optimize delivery coordination in such a way to further increase the efficiency of the logistics (Yamada et al., 2024).

Policy Recommendations

In order for AI powered drones to spread and become standardized and accepted widely, an urban air mobility (UAM) regulation framework that standard air traffic management and the drone operation guidelines must be in place (Kumar & Patel, 2024). A successful relationship between AI researchers, e-commerce companies and policymakers is required to address factors of safety, privacy and regulation, while promoting innovation (Wilson et al., 2023). In addition, governments should devise incentive programs aimed at encouraging the usage of eco-friendly autonomous delivery system to hasten the transition to ecological logistics solutions (Rahman et al., 2024 ; Ijaz et al., 2023).

Conclusion

One of the great promises of artificial intelligence (AI) applied to autonomous drone technology is its ability to change the last mile delivery into a higher, more efficient and less harmful operation. Drones have been created with the help of deep learning, reinforcement learning and computer vision to be capable of changing their navigation to be AI driven to allow them to change their route as the environment changes in real time and to be able to avoid obstacles in real time. Faster, safer, and more cost efficient delivery solution than traditional land based logistics is contributed by these advancements.

These benefits come with challenges in very wide adoption of AI powered drones which are limited by regulatory restrictions, ethical implications and technical restrictions in extreme weather conditions. To promote and enable seamless operations of drones in regulatory frameworks, the frameworks must evolve to accommodate the drones' expected operations with compliance to air traffic management systems and privacy laws (Khan & Ali, 2021). In addition, there is the problem of public acceptance and it is critical that there is transparency in AI's decision making and that safety is stringent. Future work should study how to increase the AI's adaptability, in particular in dynamic and unstructured urban environment. It is therefore important for policymakers and AI researchers, as well as logistics companies, to form a structured regulatory framework as their effort to develop ways to safely and saleably deploy autonomous drones into commercial logistics.
